3. Regression
Categories of Learning (Rep.)

- Unsupervised Learning
  - Clustering, density estimation

- Supervised Learning
  - Learning from a training data set, inference on the test data

- Reinforcement Learning
  - No supervision, but a reward function

- Discriminant Function

- Discriminative Model

- Generative Model
Categories of Learning

Unsupervised Learning
- clustering, density estimation

Supervised Learning
- learning from a training data set, inference on the test data

Reinforcement Learning
- no supervision, but a reward function

Discriminant Function
- no prob. formulation, learns a function from objects $x$ to labels $y$

Discriminative Model
- estimates the posterior $p(y_k | x)$ for each class

Generative Model
- est. the likelihoods $p(x | y_k)$ and use Bayes rule for the post.
Mathematical Formulation (Rep.)

Suppose we are given a set $\mathcal{X}$ of objects and a set $\mathcal{Y}$ of object categories (classes). In the learning task we search for a mapping $\varphi : \mathcal{X} \rightarrow \mathcal{Y}$ such that similar elements in $\mathcal{X}$ are mapped to similar elements in $\mathcal{Y}$.

Difference between regression and classification:

• In regression, $\mathcal{Y}$ is continuous, in classification it is discrete

• Regression learns a function, classification usually learns class labels

For now we will treat regression
Basis Functions

In principal, the elements of $\mathcal{X}$ can be anything (e.g. real numbers, graphs, 3D objects). To be able to treat these objects mathematically we need functions $\phi$ that map from $\mathcal{X}$ to $\mathbb{R}^N$. We call these the basis functions. We can also interpret the basis functions as functions that extract features from the input data. Features reflect the properties of the objects (width, height, etc.).
Simple Example: Linear Regression

• Assume: $X = \mathbb{R}, \ Y = \mathbb{R}, \ \phi = I$ (identity)
• Given: data points $(x_1, t_1), (x_2, t_2), \ldots$
• Goal: predict the value $t$ of a new example $x$
• Parametric formulation: $y(x, w) = w_0 + w_1 x$

\[ y \]
\[ t_5 \]
\[ t_3 \]
\[ t_4 \]
\[ t_1 \]
\[ t_2 \]
\[ x_1 \]
\[ x_2 \]
\[ x_3 \]
\[ x_4 \]
\[ x_5 \]
**Linear Regression**

To evaluate the function \( y \), we need an error function:

\[
E(w) = \frac{1}{2} \sum_{i=1}^{N} (y(x_i, w) - t_i)^2
\]

“Sum of Squared Errors”

We search for parameters \( w^* \) s.th. \( E(w^*) \) is minimal:

\[
\nabla E(w) = \sum_{i=1}^{N} (y(x_i, w) - t_i) \nabla y(x_i, w) = (0 \quad 0)
\]

\[
y(x_i, w) = w_0 + w_1 x_i \quad \Rightarrow \quad \nabla y(x_i, w) = (1 \quad x_i)
\]

Using vector notation:

\[
x_i := (1 \quad x_i)^T \quad y(x_i, w) = w^T x_i
\]

\[
\nabla E(w) = \sum_{i=1}^{N} w^T x_i x_i^T - \sum_{i=1}^{N} t_i x_i^T = (0 \quad 0) \Rightarrow w^T \sum_{i=1}^{N} x_i x_i^T = \sum_{i=1}^{N} t_i x_i^T = A^T = b^T
\]
Polynomial Regression

Now we have: \( \mathcal{X} = \mathbb{R}, \mathcal{Y} = \mathbb{R}, \phi_j(x) = x^j \)

Given: data points \((x_1, t_1), (x_2, t_2), \ldots, (x_N, t_N)\)

\[
y(x, \mathbf{w}) = w_0 + \sum_{j=1}^{N-1} w_j \phi_j(x)
\]
Polynomial Regression

We define: \[ \phi(x) := (1, \phi_1(x), \ldots, \phi_{M-1}(x))^T \]

And obtain: \[ y(x, w) = w^T \phi(x) \]

\[ E(w) = \frac{1}{2} \sum_{i=1}^{N} (w^T \phi(x_i) - t_i)^2 \]

\[ \nabla E(w) = w^T \left( \sum_{i=1}^{N} \phi(x_i) \phi(x_i)^T \right) - \sum_{i=1}^{N} t_i \phi(x_i)^T \]

“Basis functions”
Polynomial Regression

We define: \[ \phi(x) := (1, \phi_1(x), \ldots, \phi_{M-1}(x))^T \]

And obtain:

\[ y(x, \mathbf{w}) = \mathbf{w}^T \phi(x) \]

\[ E(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{N} (\mathbf{w}^T \phi(x_i) - t_i)^2 \]

\[ \nabla E(\mathbf{w}) = \mathbf{w}^T \left( \sum_{i=1}^{N} \phi(x_i) \phi(x_i)^T \right) - \sum_{i=1}^{N} t_i \phi(x_i)^T \]
Polynomial Regression

We define: \( \phi(x) := (1, \phi_1(x), \ldots, \phi_{M-1}(x))^T \)

And obtain:

\[
y(x, w) = w^T \phi(x)
\]

\[
E(w) = \frac{1}{2} \sum_{i=1}^{N} (w^T \phi(x_i) - t_i)^2
\]

\[
\nabla E(w) = w^T \left( \sum_{i=1}^{N} \phi(x_i)\phi(x_i)^T \right) - \sum_{i=1}^{N} t_i \phi(x_i)^T
\]
Polynomial Regression

Thus, we have:

$$\sum_{i=1}^{N} \phi(x_i)\phi(x_i)^T = \Phi^T\Phi$$

where

$$\Phi = \begin{pmatrix}
\phi_0(x_1) & \phi_1(x_1) & \ldots & \phi_{M-1}(x_1) \\
\phi_0(x_2) & \phi_1(x_2) & \ldots & \phi_{M-1}(x_2) \\
\vdots & \vdots & \ddots & \vdots \\
\phi_0(x_N) & \phi_1(x_N) & \ldots & \phi_{M-1}(x_N)
\end{pmatrix}$$

$$\nabla E(w) = w^T\Phi^T\Phi - t^T\Phi$$

It follows:

$$w = \Phi^+ t$$
Computing the Pseudoinverse

Mathematically, a pseudoinverse $\Phi^+$ exists for every matrix $\Phi$.

However: If $\Phi$ is (close to) singular the direct solution of $\Phi$ is numerically unstable.

Therefore: Singular Value Decomposition (SVD) is used: $\Phi = UV^T$ where

- matrices $U$ and $V$ are orthogonal matrices
- $D$ is a diagonal matrix

Then: $\Phi^+ = VD^+U^T$ where $D^+$ contains the reciprocal of all non-zero elements of $D$
A Simple Example

\[ \phi_j(x) = x^j \]

\[ N = 10 \]
\[ M = 1 \]

\[ N = 10 \]
\[ M = 3 \]

\[ N = 10 \]
\[ M = 5 \]

\[ N = 10 \]
\[ M = 10 \]
Varying the Sample Size

\[ N = 10 \]
\[ M = 10 \]

\[ N = 20 \]
\[ M = 10 \]

\[ N = 40 \]
\[ M = 10 \]

\[ N = 100 \]
\[ M = 10 \]
The Resulting Model Parameters

- $w_0$
- $w_1$
- $w_2$
- $w_3$
- $w_4$

- $w_0$
- $w_1$
- $w_2$
- $w_3$
- $w_4$
- $w_5$
- $w_6$
- $w_7$
- $w_8$
- $w_9$
Other Basis Functions

Other basis functions are possible:

- **Gaussian basis function:**
  \[ \phi_j(x) := \exp \left( -\frac{(x - \mu_j)^2}{2s^2} \right) \]

  where \[ \mu_j \triangleq \text{mean val} \]
  \[ s \triangleq \text{scale} \]

- **Sigmoidal basis function:**
  \[ \phi_j(x) := \sigma \left( \frac{x - \mu_j}{s} \right) \]

  where \[ \sigma(a) = \frac{1}{1 + \exp(-a)} \]

In both cases a set of mean values is required. These define the **locations** of the basis functions.
Gaussian Basis Functions

\[ N = 10 \]
\[ M = 1 \]

\[ N = 10 \]
\[ M = 3 \]

\[ N = 10 \]
\[ M = 5 \]

\[ N = 10 \]
\[ M = 10 \]
Sigmoidal Basis Functions

\[ N = 10 \]
\[ M = 1 \]

\[ N = 10 \]
\[ M = 3 \]

\[ N = 10 \]
\[ M = 5 \]

\[ N = 10 \]
\[ M = 10 \]
Observations

- The higher the model complexity grows, the better is the fit to the data.
- If the model complexity is too high, all data points are explained well, but the resulting model oscillates very much. It can not generalize well. This is called **overfitting**.
- By increasing the size of the data set (number of samples), we obtain a better fit of the model.
- More complex models have larger parameters.

**Problem:** How can we find a good model complexity for a given data set with a fixed size?
Regularization

We observed that complex models yield large parameters, leading to oscillation. Idea:

Minimize the error function and the magnitude of the parameters simultaneously

We do this by adding a regularization term:

$$\tilde{E}(w) = \frac{1}{2} \sum_{i=1}^{N} (w^T \phi(x_i) - t_i)^2 + \frac{\lambda}{2} \|w\|^2$$

where $\lambda$ rules the influence of the regularization.
Regularization

As above, we set the derivative to zero:

$$\nabla \tilde{E}(w) = \sum_{i=1}^{N} (w^T \phi(x_i) - t_i) \phi(x_i)^T + \lambda w^T = 0^T$$

$$w^T \Phi^T \Phi + \lambda w^T = t^T \Phi \quad \Rightarrow \quad (\lambda I + \Phi^T \Phi)w = \Phi^T t$$

$$w = (\lambda I + \Phi^T \Phi)^{-1} \Phi^T t$$

With regularization, we can find a complex model for a small data set. However, the problem now is to find an appropriate regularization coefficient $\lambda$. 
Regularized Results

\[ N = 10 \]
\[ M = 10 \]
\[ \lambda = 1 \]

\[ N = 10 \]
\[ M = 10 \]
\[ \lambda = 10^{-3} \]

\[ N = 10 \]
\[ M = 10 \]
\[ \lambda = 10^{-6} \]

\[ N = 10 \]
\[ M = 10 \]
\[ \lambda = 10^{-11} \]
The Problem from a Different View

Assume that $y$ is affected by Gaussian noise:

$$t = y(x, w) + \epsilon \quad \text{where} \quad \epsilon \sim \mathcal{N}(.; 0, \sigma^2)$$

Thus, we have

$$p(t \mid x, w, \sigma) = \mathcal{N}(t; y(x, w), \sigma^2)$$
Maximum Likelihood Estimation

Aim: we want to find the $w$ that maximizes $p$.

$p(t \mid x, w, \sigma)$ is the **likelihood** of the measured data given a model. Intuitively:

Find parameters $w$ that maximize the probability of measuring the already measured data $t$.

“Maximum Likelihood Estimation”

We can think of this as fitting a model $w$ to the data $t$.

Note: $\sigma$ is also part of the model and can be estimated. For now, we assume $\sigma$ is known.
Maximum Likelihood Estimation

Given data points: \((x_1, t_1), (x_2, t_2), \ldots, (x_N, t_N)\)

Assumption: points are drawn independently from \(p\):

\[
p(t \mid x, w, \sigma) = \prod_{i=1}^{N} p(t_i \mid x, w, \sigma) = \prod_{i=1}^{N} \mathcal{N}(t_i; w^T \phi(x_i), \sigma^2)
\]

where:

\[
x = (x_1, x_2, \ldots, x_N)
\]
\[
t = (t_1, t_2, \ldots, t_N)
\]

Instead of maximizing \(p\) we can also maximize its logarithm (monotonicity of the logarithm)
Maximum Likelihood Estimation

\[ \ln p(t \mid x, w, \sigma) = \sum_{i=1}^{N} \ln p(t_i \mid x, w, \sigma) \]

\[ = \frac{1}{2} \sum_{i=1}^{N} - \ln(\sigma^2) - \ln(2\pi) - \frac{1}{\sigma^2} (w^T \phi(x_i) - t_i)^2 \]

\[ = - \frac{N(\ln(\sigma^2) + \ln(2\pi))}{2} \]

\[ \mathcal{N} \rightarrow \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2} \frac{(x-\mu)^2}{\sigma^2}} \]

The parameters that maximize the likelihood are equal to the minimum of the sum of squared errors.
Maximum Likelihood Estimation

\[ \ln p(t \mid x, w, \sigma) = \sum_{i=1}^{N} \ln p(t_i \mid x, w, \sigma) \]

\[ = \frac{1}{2} \sum_{i=1}^{N} - \ln(\sigma^2) - \ln(2\pi) - \frac{1}{\sigma^2} (w^T \phi(x_i) - t_i)^2 \]

\[ = -\frac{N(\ln(\sigma^2) + \ln(2\pi))}{2} - \frac{1}{\sigma^2} \sum_{i=1}^{N} (w^T \phi(x_i) - t_i)^2 \]

\[ w_{ML} := \arg \max_w \ln p(t \mid x, w, \sigma) = \arg \min_w E(w) = (\Phi^T \Phi)^{-1} \Phi^T t \]

The ML solution is obtained using the Pseudoinverse
Maximum A-Posteriori Estimation

So far, we searched for parameters $\mathbf{w}$, that maximize the data likelihood. Now, we assume a Gaussian prior:

$$p(\mathbf{w} \mid \sigma_2) = \mathcal{N}(\mathbf{w}; \mathbf{0}, \sigma_2 \mathbf{I})$$

Using this, we can compute the posterior (Bayes):

$$p(\mathbf{w} \mid x, t, \sigma_1, \sigma_2) \propto p(t \mid x, \mathbf{w}, \sigma_1) p(\mathbf{w} \mid \sigma_2)$$

"Maximum A-Posteriori Estimation (MAP)"
Maximum A-Posteriori Estimation

So far, we searched for parameters $w$, that maximize the data likelihood. Now, we assume a Gaussian prior:

$$p(w | \sigma_2) = \mathcal{N}(w; 0, \sigma_2 I)$$

Using this, we can compute the posterior (Bayes):

$$p(w | x, t, \sigma_1, \sigma_2) \propto p(t | x, w, \sigma_1)p(w | \sigma_2)$$

strictly:

$$p(w | x, t, \sigma_1, \sigma_2) = \frac{p(t | x, w, \sigma_1)p(w | \sigma_2)}{\int p(t | x, w, \sigma_1)p(w | \sigma_2) dw}$$

but the denominator is independent of $w$ and we want to maximize $p$. 
Maximum A-Posteriori Estimation

\[
\ln p(w \mid x, t, \sigma_1, \sigma_2) \propto \ln p(t \mid x, w, \sigma_1) + \ln p(w \mid \sigma_2)
\]

\[
\text{const.} - \frac{1}{\sigma_1^2} \sum_{i=1}^{N} (w^T \phi(x) - t_i)^2
\]

\[
\propto -\frac{1}{\sigma_1^2} \left( \sum_{i=1}^{N} (w^T \phi(x) - t_i)^2 + \frac{\sigma_1^2}{\sigma_2^2} w^T w \right)
\]

This is equal to the regularized error minimization.

The MAP Estimate corresponds to a regularized error minimization where \( \lambda = \left( \frac{\sigma_1}{\sigma_2} \right)^2 \).
Summary

- Regression is a method to find a mathematical model (function) for a given data set.
- Regression can be done by minimizing the sum of squared (SSE) errors, i.e. the distances to the data.
- Maximum-likelihood estimation uses a probabilistic representation to fit a model into noisy data.
- Maximum-likelihood under Gaussian noise is equivalent to SSE regression.
- Maximum-a-posteriori (MAP) estimation assumes a (Gaussian) prior on the model parameters.
- MAP is solved by regularized regression.
Bayesian Linear Regression
Bayesian Linear Regression

• Using MAP, we can find optimal model parameters, but for practical applications two questions arise:
  • What happens in the case of sequential data, i.e. the data points are observed subsequently?
  • Can we model the probability of measuring a new data point, given all old data points? This is called the **predictive distribution**:

\[ p(t \mid x, t', x') \]
When Bayes Meets Gauß

If we are given this:

I. \( p(x) = \mathcal{N}(x \mid \mu, \Sigma_1) \)

II. \( p(y \mid x) = \mathcal{N}(y \mid Ax + b, \Sigma_2) \)

Then it follows (properties of Gaussians): 

III. \( p(y) = \mathcal{N}(y \mid A\mu + b, \Sigma_2 + A\Sigma_1 A^T) \)

IV. \( p(x \mid y) = \mathcal{N}(x \mid \Sigma(A^T\Sigma_2^{-1}(y - b) + \Sigma_1^{-1}\mu), \Sigma) \)

where

\[
\Sigma = (\Sigma_1^{-1} + A^T\Sigma_2^{-1}A)^{-1}
\]

"Linear Gaussian Model"
Sequential Data

Given: Prior mean $m_0$ and covariance $S_0$, noise covariance $\sigma$  

\[ p_0(w \mid S_0) = \mathcal{N}(w; m_0, S_0) \]

1. Set $i = 0$

2. Observe data point $(x_i, t_i)$

3. Formulate the likelihood $p(t_i \mid x_i, w)$ as a function of $w$ (= Gaussian with mean $\phi(x_i)^T w$ and covariance $\sigma$)

4. Multiply the likelihood with the prior $p_i(w \mid S_i)$ and normalize (= Gaussian with $m_{i+1}$ and $S_{i+1}$)

5. This results in a new prior $p_{i+1}(w \mid S_{i+1})$

6. Go back to 1. if there are still data points available
Comparison: the Standard Bayes Filter

\[
\text{Bel}(x_t) = p(x_t \mid u_1, z_1, \ldots, u_t, z_t)
\]

(Bayes) \quad = \eta \ p(z_t \mid x_t, u_1, z_1, \ldots, u_t) p(x_t \mid u_1, z_1, \ldots, u_t)

(Markov) \quad = \eta \ p(z_t \mid x_t) \int p(x_t \mid u_1, z_1, \ldots, u_t, x_{t-1}) p(x_{t-1} \mid u_1, z_1, \ldots, u_t) dx_{t-1}

(Tot. prob.) \quad = \eta \ p(z_t \mid x_t) \int p(x_t \mid u_t, x_{t-1}) p(x_{t-1} \mid u_1, z_1, \ldots, u_t) dx_{t-1}

(Markov) \quad = \eta \ p(z_t \mid x_t) \int p(x_t \mid u_t, x_{t-1}) p(x_{t-1} \mid u_1, z_1, \ldots, z_{t-1}) dx_{t-1}

(Markov) \quad = \eta \ p(z_t \mid x_t) \int p(x_t \mid u_t, x_{t-1}) \text{Bel}(x_{t-1}) dx_{t-1}
Comparison: the Standard Bayes Filter

\[
\text{Bel}(x_t) = p(x_t \mid u_1, z_1, \ldots, u_t, z_t)
\]

(Bayes)

\[
= \eta p(z_t \mid x_t, u_1, z_1, \ldots, u_t) p(x_t \mid u_1, z_1, \ldots, u_t)
\]

(Markov)

\[
= \eta p(z_t \mid x_t) p(x_t \mid u_1, z_1, \ldots, u_t)
\]

Note: Different Notation!
A Simple Example

Our aim is to **fit a straight line** into a set of data points. Assume we have:

Basis functions are equal to identity: \( \phi(x) = x \)

Prior mean is zero, prior covariance: \( \sigma_2^2 = 0.5 \), noise variance is: \( \sigma_1^2 = 0.2^2 \)

Ground truth is: \( f(x, a) = a_0 + a_1 x \) where \( a_1 = 0.5 \) \( a_0 = -0.3 \)

Data points are sampled from ground truth

Thus:

We want to recover \( a_0 \) and \( a_1 \) from the sequentially incoming data points \( (x_1, t_1), (x_2, t_2), \ldots \)

The Predictive Distribution

We obtain the predictive distribution by integrating over all possible model parameters:

\[ p(t \mid x, t, x) = \int p(t \mid x, w)p(w \mid x, t)dw \]

New data likelihood \hspace{1cm} Old data posterior

As before the posterior is prop. to the likelihood times the prior. But now, we don’t maximize. The posterior can be computed analytically, as the prior is Gaussian.

\[ p(w \mid x, t) = \mathcal{N}(w \mid m_N, S_N) \]

where

\[ S_N^{-1} = S_0^{-1} + \sigma^{-2}\Phi^T\Phi \]

Prior cov

\[ w_N = S_N(S_0^{-1}m_0 + \sigma^{-2}\Phi^Tt) \]

Prior mean
The Predictive Distribution

Using formula III. from above (linear Gaussian),

\[ p(t \mid x, t, x) = \int p(t \mid x, w)p(w \mid x, t)dw \]

\[ = \int \mathcal{N}(t; w^T \phi(x), \sigma)\mathcal{N}(w; m_N, S_N) \]

\[ = \mathcal{N}(t; m_N^T \phi(x), \sigma_N^2(x)) \]

where

\[ \sigma_N^2(x) = \sigma^2 + \phi(x)^T S_N \phi(x) \]

Summary

- Regression can be expressed as a **least-squares** problem.
- To avoid overfitting, we need to introduce a **regularisation term** with an additional parameter $\lambda$.
- Regression **without** regularisation is equivalent to Maximum Likelihood Estimation.
- Regression **with** regularisation is Maximum A-Posteriori.
- Bayesian Linear Regression operates on **sequential** data and provides the **predictive distribution**.
- When using Gaussian priors (and Gaussian noise), all computations can be done **analytically**.
